

Chapter 1: Introduction to Databases

A database is an organized collection of data.

It can be easily stored, managed and accessed.

A database management system or DBMS is the software used to create and manage databases.

Examples include MySQL, Oracle and SQL Server.

Tables store data in rows and columns.

A primary key uniquely identifies each record.

Chapter 2: Normalization

Normalization reduces data redundancy.

It organizes data into related tables.

First normal form removes repeated groups.

Second normal form removes partial dependencies.

Third normal form removes transitive dependencies.

Foreign keys link tables together.

The ER model uses entities and relationships.
